# A LIBRARY-BASED REFERENCE SERVICE FOR MACHINE-READABLE CENSUS DATA:

THE CANADIAN EXPERIENCE

Slavko Manojlovich

University of Windsor

Windsor, Ontario

The Census of Canada is a prime patron's request for census inforsource for the demographic, social, mation required a consideration, on economic and housing data used in the part of the librarian, of both social science research. Only a the hard-copy and the M-R census small proportion of the available census data is published in hardcopy form. If we add to this the growing use of computers for data analysis we can see that the machine-readable (M-R) version of the census is becoming increasingly more important to researchers. The library is the major depository of information on the university campus with the librarian acting as an available intermediary between the patron's informational needs and the library's resources. This paper will attempt to examine the place of the M-R census within the academic library. This will be followed by a discussion of the potential problems and pitfalls which librarians and researchers alike may encounter in making use of the M-R census.

#### THE M-R CENSUS AND THE ACADEMIC LIBRARY ,

The Census of Canada first became available in M-R form in 1961 with the production of the User Summary Tapes (U.S.T.). In 1971 the Public Use Sample Tapes (P.U.S.T.) were produced in response to the researcher's need for micro-data. For those libraries which had access to the M-R census tapes the referencing of the

resources.

The importance of the latter is evident in the following situations:

> 1. The requested data is not abailable in a printed publication but may be retrieved from a census tape. Since the census bulletins provide summary data for a limited number of standard geographic regions, they are unable to satisfy data requestes for small municipalities. subdivisions of these municipalities, or usercreated geographic areas. City planning districts are an example of the latter. The major feature of the U.S.T. (enumeration area series) is that the record is based upon the enumeration area (E.A.). This is the smallest geographic unit of analysis allowed by the principle of confidentiality which governs the dissemination of census data. Furthermore. since E. A. boundaries never cross those of larger recognized statisti

IASSIST Newsletter, Vol. 3, No. 3 (Summer 1979)

complete a description as indicated by the Statistics Canada information.

c) Furthermore, these respondents were asked, "Who processes the user's request for information from tape?". The majority response was the com-puter centre (33%), followed by the data

archive (20%) through the co-operative effort of the library and the computer centre (13). The remaining 33% responded with a variation of the user himself, with or without the assistance of faculty members in certain departments. (i.e. geography or sociology).

TABLE 1

Do you have any machine-readable census tapes on your campus?

SIZE OF HOLDINGS

	-		
	MAJOR	OTHER	TOTAL
YES	8	7	56% (15)
NO	7	5	44% (12)
			100% (27)
		YES 8	YES 8 7

These observations clearly indicate that the overwhelming majority library's position with respect to of academic libraries are not actively involved in providing user it is more likely that this is access to the M-r census resources merely a reflection of which are located in the computer library's traditional indifference facility's tape library. Either towards M-R information including the library is not aware of the data files and computer programmes. existence of the M-R census tapes The addition of a chapter on M-R or, if it is, the processing of the data files in the latest edition of data from tape is performed by a the Anglo-American Cataloguing campus facility other than the Rules (AACRII) should foster a library. According to Statistics willingness on the part of the Canada information, the M-R census library to accept the university's tapes were rarely ordered by the M-R resources as a legitimate part library. Requests were made by of the library's holdings. either the computer centre or by individual faculty members. This

could possibly account for the the M-R census. On the other hand, the transfer of entire data files to a patron's disc area by the data archive are both examples of secondary data reference. In either case, the patron is provided with the means for obtaining the desired information but not with the information, itself. An attempt to expand their services to include primary data reference would not be reasonable in light of their need to acquire adequate support documentation.

The library has the personnel and the resources to provide a primary data reference service for the M-R census. The success of this venture depends on the following conditions:

- The university community must recognize thelibrary as the resource centre for all census information, M-R and hard-copy. Thus, the library should be prepared to promote its expanded service by conducting several information and training seminars for faculty, staff and students on the availability and use of the M-R census.
- The library will need to take an inventory of the M-R census tapes currently available on campus and should co-ordinate the future acquisition of tapes. Statistics Canada information indicated that 25% of the institutions with major holdings had acquired multiple copies of the tapes, an unnecessary added expense if you consider that the tapes are stored in the computer centre®s tape library. At these

institutions tape requests were made by as many as 8 departments.

3. The majority of the libraries have a hardcopy computer terminal which they can use to acces the university's computer. However, the processing of user requests will require some staff training in elementary programming. An introductory course in a programming language such as PL/1 will more than satisfy the computer expertise necessary for massaging data from tape. A mini-session on the use of a statistical package such as SAS would also be helpful.

A library-based reference service for the M-R census has distinct advantages for the census user. First, the patron's request is directed to an integrated hardcopy and M-R census collection. Second, the request is processed by a reference librarian who is qualified in the art of query negotiation. The remainder of this paper will focus upon the problems which may arise in the referencing and use of the M-R census.

# THE M-R CENSUS: PROBLEMS AND SOLUTIONS

Thelogical analysis of a typical census query into its component parts can provide us with a framework for comprehending the underlying problems associated with referencing census summary data. Statistics Canada has developed the PGRST classification as the basis of an indexing and retrieval system

### IASSIST Newsletter, Vol. 3, No. 3 (Summer 1979)

major realignment of boundaries. Witness the recent emergence of the "regional municipality" which replaced certain counties in the province of Ontario.

c) Code - A geographic area is identified in the M-R census via an assigned code. The introduction of the "Standard Geographical Classification" in 1975 produced a complete revision of these codes in the 1976 census-[16]

> The identification of these potential changes is hampered by the fact that a geographic level of analysis may lie within the jurisdictional control of one of a number of government bodies. For example, E.A. and census tract boundaries are determined by Statistics Canada, whereas municipal boundaries are within provincial control. Since there is no single document which describes these geographic changes in the required level of detail one is forced to consult the appropriate publications of the respective government cepartments and agencies.

The · "Official Lists" of each census identify geographic areas in terms of E.

A. \*s. [17] Theoretically, this would enable a user to create a comparable area over census years. Unfortunately, correspondence lists for enumeration areas reveal that the nature of the boundary modifications do not permit the identification of equivalent units in all cases.[18] Statistics Canada does provide special tabulations for user-specified areas from the Census Master Data File should this become necessary.

d) Time: A major census is conducted every 10 years witha mini-census occurring at the 5-year interval. The next major census will be in 1981. It is sufficient to note that the mini-census contains only the core demographic questions and some additional housing or economic questions.

# CONCLUSION

The first section of this paper described the current situation surrounding the accessibility of the M-R census at Canadian universities and made a case for the creation of a centralized census data reference service within the library. The discussion of the problems related to census data use underscored the need for a library or information professional to assist the researcher in the acquiIASSIST Newsletter, Vol. 3, No. 3 (Summer 1979)

ROUND II DELPHI QUESTIONNAIRE INSTRUCTIONS

# PLEASE READ CAREFULLY

In the last issue of the <u>Newsletter</u> you were asked to respond to Round I of a Delphi study designed to aid our thinking about future developments relating to the distribution and archiving of machine readable data. That questionnaire was completely open-ended and was structured to elicit the ideas and concerns (in a number of categories) of the members of IASSIST. The responses from Round I were used in the development of the ouestionnaire presented in this issue -- a closed questionnaire consisting of forty-five "event" statements.

For this Round of the Delphi we are asking that you respond to each event statement with three different ratings or "Guestions" (designated Question 1, Question 2, and Question 3). Guestions 1 and 3 are seven point rating scales extending from "Low" to "High". Question 2 requests that you make an estimate of the Year in which the event will take place or begin. With these three Questions we are attempting to do the following:

- Assess the importance of each event to the members of IASSIST (Question 1).
- Forecast the approximate date by which the event will occur or begin to change (Question 2).
- Estimate the likelihood that the event will actually occur (Question 3).

When the data are evaluated, median ratings on each of the three questions will be used as an estimate of the collective viewpoint of the IASSIST membership.

When using the seven point ratings scales for Guestions 1 and 3 the scales should be interpreted as follows:

- 1. Very low importance or likelihood.
- 2. Moderately low importance or likelihood.
- 3. Low importance or likelihood.
- 4. Neutral importance or likelihood (a 50/50 chance).
- 5. High importance or likelihood.
- 6. Moderately high importance or likelihood.
- 7. Very high importance or likelihood.

To use the scales, simply CIRCLE the number which best approximates your viewpoint concerning the event statement.

Our primary concern is in forecasting directions in the nineteen eighties so your estimates of dates should generally be in the time period 1980 - 1990. It may be, however, that for a particular event you believe that the date will be later than 1990 - if so, indicate the date. If you think the event will never happen, enter "9999" as the
